

Overview of the Analytics Manager

Script:

The first part of our module is the Analytics Manager. The overall goal of this class is to provide a central location to store all logging related data for our analytics module. Instead of having stats managed in several different locations of the game, this class provides easy access to all relevant data.

The data in this class is logged and stored through DataLogs and ActionLogs. The data logs are used for tracking numeric data over time. In our Module for example, we are using them to keep track of stats like damage dealt and enemies killed in the game.

The second form of data collection is through the Action log which is used to track Agent and Player related actions through the game. This is also helpful for the Replay driver which can be used to replay logged actions.

These logs are also used by the StatsTracker class which reads the data in these logs to calculate summaries of the data which are then passed to the game class to be displayed

Another important part of the Analytics Manager is that it uses simple logging functions for the rest of the game to call. So when some event happens in the game, such as damage dealt or an enemy getting killed, the game can call the matching logging function.

Overall this design keeps the analytics manager organized and it makes the module easier to expand later to track other stats without altering how the game works with the analytics module.
